Py-init?

HOW TO UNIT TEST

from unittest import TestCase

Separate tests from application code

class TestBakeryObject(TestCase):

pass

self.assertEqual
↓
usually

this prevents the whole program from crashing because they run individually

=> we got an individual button

How to properly write tests

- > PyUnit -> member of xUnit testing tools. (JUnit for Java the first one)
- > unit tests should be placed in their own package (called "test").
- > unit test classes must be derived from unittest.TestCase -> assertX methods (>)
- > test method names must start with "test_"
- > they run separately from the program.

Check unit tests -> only then tries to build the code -> ...

! You need automatic testing unit testing?

complete build

Test Discovery → "D Run Python tests in test..." → test package
 → automatic testing
 → right click → ...

How do I know I have enough tests?

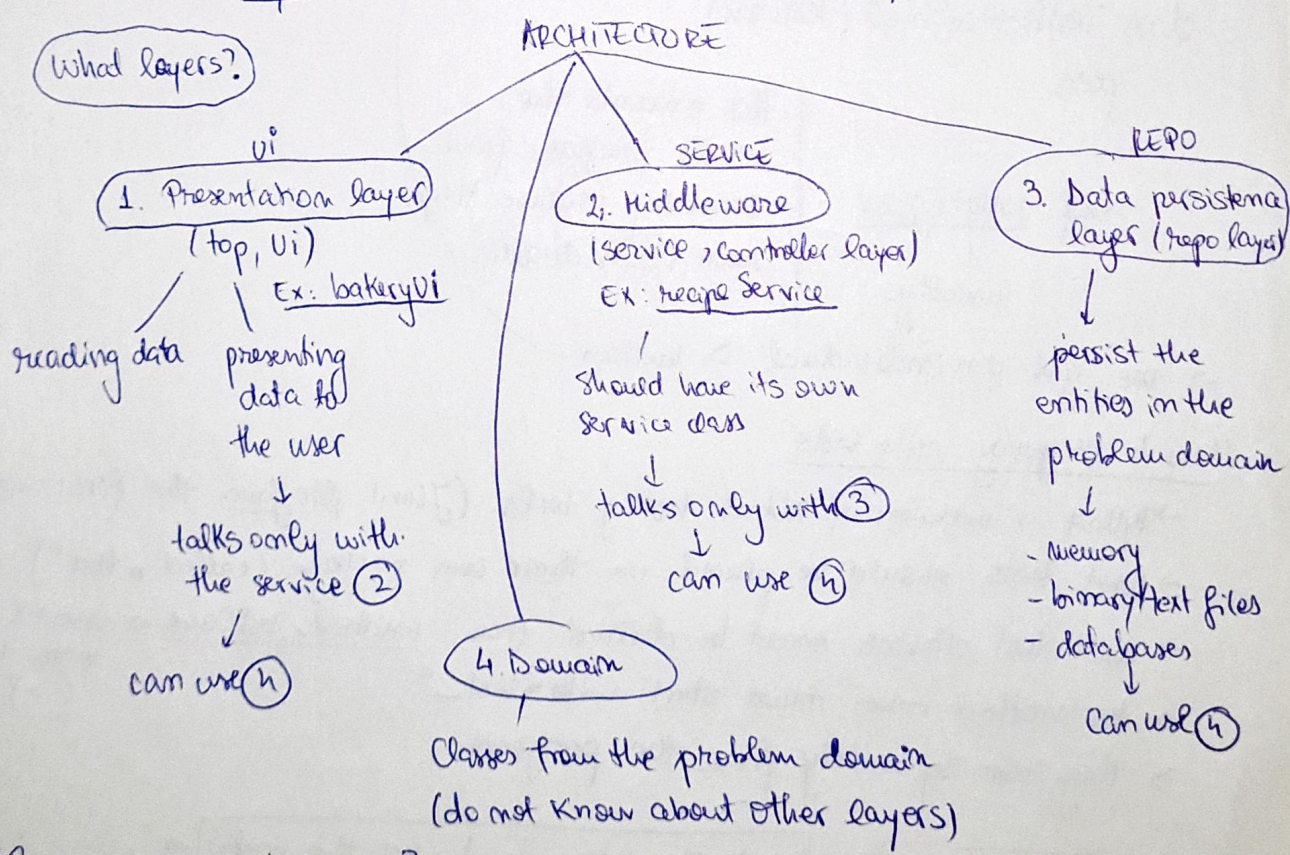

"CODE COVERAGE" → how much(%) of the app has been already tested?
 ↓ "Run... Coverage"
 the more, the better. (but not perfect because 100% could also mean bugs)
 "BRANCH COVERAGE" → count by branches.

Layered architecture

What is it? = DESIGN PATTERN for writing large programs

- ↳ the program is made out of layers
- ↳ each layer has access for classes in its own layer, or the layer...

What layers?

Save recipes one by one ? → Product defined by an ID → when I load them back I have a problem. why → we save the same thing in two ≠ places.
 ↳ Solution: `txt_file_repo.py` → `def load_file(self)`
